# Agenda

- 1 Motivation
- 2 The Convolution Operation
- 3 Hyperparameters & Arithmetic
- 4 CNN Building Blocks
- 5 MATLAB Implementation
- 6 Conclusion

# Biological Inspiration

CNNs are biologically inspired by the visual cortex organization (Hubel & Wiesel, 1959).

- Local Receptive Fields: Neurons respond only to a small sub region of the visual field.
- Hierarchy:
- **V1 Area:** Detects simple edges and orientations.
- **Higher Areas:** Detect shapes, textures, and objects.

Figure 1: Hierarchical processing in the brain vs. Deep Learning.

# Why not Standard MLPs?

Imagine an image of  $224 \times 224$  pixels (RGB).

## The Curse of Dimensionality

If we flatten this image into a vector:

$$\text{Input Vector} = 224 \times 224 \times 3 = 150,528 \text{ inputs}$$

If the first hidden layer has 1,000 neurons (Dense Layer):

$$\text{Weights} = 150,528 \times 1,000 \approx 150 \text{ Million Parameters!}$$

**Problem:** Huge computational cost and massive overfitting.

**Solution:** Local connectivity and Parameter Sharing (CNNs).

- 6 Conclusion

# The Mathematical Definition

In Deep Learning, a "convolution" is technically a **sliding dot product** (cross-correlation).

We pass a filter (kernel)  $K$  over an image  $I$ :

$$(I * K)(i, j) = \sum_m \sum_n I(i + m, j + n) \cdot K(m, n) \quad (1)$$

- **Element-wise multiplication:** Between the kernel weights and the image patch.
- **Summation:** Aggregating the result into a single pixel in the Feature Map.

# Feature Maps & Channels

Input Tensor ( $H \times W \times C_{in}$ )

An image usually has 3 channels (RGB).

Output Tensor ( $H' \times W' \times K$ )

If we apply  $K$  distinct filters (e.g., 32 filters):

- We obtain 32 discrete 2D maps.
- These stack together to form the output depth (Channels).
- **Analogy:** Each channel represents a specific "feature" (one for horizontal lines, one for

# Spatial Dimensions Control

How do we calculate the output size of a layer? This is the fundamental arithmetic equation for CNN design.

$$O = \left\lfloor \frac{W - F + 2P}{S} \right\rfloor + 1 \quad (2)$$

Where:

- $W$ : Input Volume Size (Width/Height)
- $F$ : Filter /Kernel Size (e.g.,  $3 \times 3$ )
- $S$ : **Stride** (Step size of the slide)
- $P$ : **Padding** (Zeros added around the border)

# Padding Options

## 1. Valid Padding ( $P = 0$ ):

- No padding.
- The image shrinks after convolution.
- Losing edge information.

## 2. Same Padding ( $P > 0$ ):

- Padding added to preserve dimensions.
- Output Size = Input Size (if stride=1).
- Allows for very deep networks without vanishing spatial size.

**MATLAB syntax:** "Padding", "same" vs "Padding", 0

- 6 Conclusion

# The Non-Linearity (ReLU)

Convolution is a *linear* operation (multiplication + sum). To learn complex patterns, we need non-linearity.

$$f(x) = \max(0, x) \quad (3)$$

## Rectified Linear Unit (ReLU):

- Introduces sparsity.
- Avoids Vanishing Gradient problem (common in Sigmoid).
- Extremely computationally efficient.

# Pooling Layers (Subsampling)

Purpose: Progressively reduce the spatial size ( $S$ -dimension) to reduce parameters and computation.

- **Max Pooling:** Takes the maximum value in the window. Extracts the most prominent features.
- **Average Pooling:** Takes the average. Smooths features.

**Key Property:** *Translation Invariance*. Small shifts in the image don't change the outcome.

Placeholder: 2x2 Max Pooling on

# Flattening & Fully Connected

## Transition to Classification

After extracting spatial features with Convolution+Pooling, we get a 3D volume (e.g.,  $7 \times 7 \times 512$ ).

- 1 **Flatten:** Unroll the volume into a 1D vector (size 25,088).
- 2 **Fully Connected (FC):** Standard MLP layers to combine features and perform classification logic.
- 3 **Softmax:** Probability distribution for the output classes.

# Defining a CNN in MATLAB

Using the Layer Graph approach (standard for modern image classification):

Listing 1: Standard VGG-Style Block

```
1 inputSize = [28 28 1]; % Grayscale image (S-S-C)
2
3 layers = [
4     imageInputLayer(inputSize, "Name", "imageinput")
5
6     % Convolutional Block 1
7     convolution2dLayer(3, 8, "Padding", "same", "Name", "conv_1")
8     batchNormalizationLayer("Name", "batchnorm_1")
9     reluLayer("Name", "relu_1")
10
11    % Downsampling
12    maxPooling2dLayer(2, "Stride", 2, "Name", "maxpool_1")
13
14    % Classification Head
15    fullyConnectedLayer(10, "Name", "fc") % 10 classes
```

# Understanding Data Formats: SSCB

When training CNNs, MATLAB (since R2023a) usually expects tensors in the format **SSCB**.

- **S (Spatial)**: Height ( $H$ ).
- **S (Spatial)**: Width ( $W$ ).
- **C (Channels)**: Depth (Colors or Feature Maps).
- **B (Batch)**: Number of images processed in parallel.

$$Tensor = 224 \times 224 \times 3 \times 32$$

# Agenda

- 1 Motivation
- 2 The Convolution Operation
- 3 Hyperparameters & Arithmetic
- 4 CNN Building Blocks
- 5 MATLAB Implementation
- 6 Conclusion**

# Summary

- **Convolution** exploits spatial hierarchies and shared weights, making image processing efficient.
- **ReLU** provides the necessary non-linearity for deep learning.
- **Pooling** reduces dimensionality and grants translation invariance.
- **Architecture:** It is a game of managing Dimensions ( $S$ ) and Channels ( $C$ ) usually decreasing spatial size while increasing channel depth deep in the network.
